Difference Between RIPv1 And RIPv2

RIPv1	RIPv2
· It is classful, meaning it does not send subnet mask information in its update. It assumes default class boundaries (Class A, B, C)	It is classless, meaning it includes subnet mask information, allowing ~~sup~~ support for VLSM and CIDR, which makes it much more flexible for modern network design.
· It sends update using broadcast to all devices in the network	· It uses multicast (224.0.0.9), so only RIP-enabled routers process the updates.
· It does not support authentication	· It supports authentication, both plain text and MD5. This makes it more secure.
· It performs automatic summarization only and it cannot be disabled	· Supports both automatic and manual summarization, and you can disable auto-summarization
· It does not support discontiguous networks properly due to lack of subnet information	· Supports discontiguous networks because it carries subnet masks.
· It does not include next-hop information in updates	It includes next-hop information in updates, improving routing efficiency.
